Central Picture

The removed fibrin mass from the left ventricular cavity.

Central Message

Use of fibrin glue in left ventriculoplasty can be dangerous. The recommendations for fibrin glue and intraoperative TEE are vital. The prophylactic use of fibrin glue should be reconsidered.
Introduction

FG is widely used in cardiac surgery and considered to be safe. Herein, we report a case in which FG used to attain hemostasis of the suture line in left ventriculoplasty leaked into the left ventricular cavity as a floating mass.

Case presentation

A 66-year-old man was brought to our department because of a pseudoaneurysm in the posterior wall of the left ventricle (Fig. 1). He had undergone an extended sandwich patch procedure three years prior for a post-MI VSP due to an occlusion of the RCA. Although there were no symptoms, he underwent urgent surgery due to the risk of rupture.

The patient underwent a median sternotomy. CPB was established via the ascending aorta and right atrium. The aorta was clamped and antegrade cold blood cardioplegia was administered intermittently (Video). When the pseudoaneurysm was incised, a large thrombus was found. The patch on the left ventricular side, which was the orifice of the pseudoaneurysm, was semi-circumferentially detached. The orifice was located near the posterior papillary muscle and was subsequently closed using a Dacron patch with double sutures. Beriplast P (CSL Behring K.K., Tokyo, Japan) was applied to suture line with fibrinogen solution and thrombin solution in that order, then Biogluve (Cryolife Inc., Atlanta,
GA, USA) was applied. The outer wall of the pseudoaneurysm was closed, the aorta was de-clamped, and the heartbeat resumed spontaneously.

The TEE revealed a floating structure around the aortic valve. It was thought that the mitral chorda tendinea were partially ruptured. However, after the second cardioplegic arrest, an incision was made on the right side of the left atrium and a 3 × 20 mm FM was found in the left ventricle. The mass was removed, then the aorta was de-clamped. However, the TEE revealed a structure attached to the back of the anterior leaflet of the mitral valve. After the third cardioplegic arrest, the left ventricular cavity was observed through the aortic valve and a 5 × 10 mm FM was found attached to the papillary muscle of the anterior leaflet of the mitral valve. The mass was removed. During the surgery, heparin was administered to keep the ACT over 400 seconds, and protamine was administered after the second FM removal.

Images of the removed masses are shown in Fig. 2. The TEE revealed no abnormal structures; therefore, surgery was completed. The postoperative course was uneventful, and the patient was discharged unaided on postoperative day 16.

**Discussion**

FG is widely used for hemostasis, and its usefulness has been reported. However, the routine use of FG and the necessary precautions to ensure safety need further examination. A systematic review and meta-analysis by Daud et al. showed that the use of FG significantly reduced the blood loss and operative time. However, no significant differences in the
postoperative blood transfusion volume, reoperation rate, or 30-day mortality were observed.

Thus, the study suggested that FG should be used selectively rather than routinely in cardiovascular surgery. The use of FG in CABG can reportedly increase the 30-day mortality. Based on these reports, the routine use of FG is not recommended.

We experienced the FG applied to the outside of the heart infiltrating the inside of the heart. A similar report described that the FG applied at the anastomosis of a synthetic vessel graft leaked into the aorta and adhered to the aortic valve, emphasizing the importance of a comprehensive TEE study before weaning from CPB. To avoid serious complications when FG is used, we should evaluate for foreign bodies and other abnormalities.

In this case, the FG was applied without reducing the suction pressure of the left ventricular vent. This negative suction pressure might have caused FG leakage into the cardiac cavity. Additionally, the amount of glue applied may have been too much; therefore, it may be better to apply a small amount and add more if insufficient. Having the anastomosed structure filled with blood may be effective too. Minato et al. also studied the use of FG for needle holes and found that the rub-and-spray method, i.e., rubbing solution A (containing fibrinogen) on the needle holes, followed by spraying both A and B solutions (containing thrombin and calcium chloride) using an application nozzle, had the best hemostatic effect. The thrombus formation could be prevented by a specific polymerization reaction of the fibrin by spraying solutions A and B. Despite these improvements, one
should be aware of the potential risk of embolic complications caused by FG, and the prophylactic application of FG in left ventriculoplasty should be evaluated further.

Informed consent was obtained orally to submit and publish this report.
